

9.6 Class Object

As we discussed earlier in this chapter, all classes in Java inherit directly or indirectly from class `Object` (package `java.lang`), so its 11 methods (some are overloaded) are inherited by all other classes. [Figure 9.12](#) summarizes `Object`'s methods. We discuss several `Object` methods throughout this book (as indicated in [Fig. 9.12](#)).

Method	Description
<code>equals</code>	This method compares two objects for equality and returns <code>true</code> if they're equal <code>false</code> otherwise. The method takes any <code>Object</code> as an argument. When objects of a particular class must be compared for equality, the class should override method <code>equals</code> to compare the contents of the two objects. For the requirements of implementing this method (which include also overriding method <code>hashCode</code>), refer to the method's documentation at http://docs.oracle.com/javase/8/docs/api/java/lang/Object#equals(Object) . The default <code>equals</code> implementation uses operator <code>==</code> to determine whether two references refer to the same object in memory. Section 14.3.3 demonstrates class <code>String</code> 's <code>equals</code> method and differentiates between comparing <code>String</code> objects with <code>==</code> and with <code>equals</code> .
<code>hashCode</code>	Hashcodes are <code>int</code> values used for high-speed storage and retrieval of information in a hashtable data structure (see Section 16.10). This method is also called as part of <code>Object</code> 's default <code>toString</code> method implementation.
<code>toString</code>	This method (introduced in Section 9.4.1) returns a <code>String</code> representation of an object. The default implementation of this method returns the package name and class name of the object's class typically followed by a hexadecimal representation of the value returned by the object's <code>hashCode</code> method.
<code>wait</code> , <code>notify</code> , <code>notifyAll</code>	Methods <code>notify</code> , <code>notifyAll</code> and the three overloaded versions of <code>wait</code> are related to multithreading, which is discussed in Chapter 23 .
<code>getClass</code>	Every object in Java knows its own type at execution time. Method <code>getClass</code> (used in Sections 10.5 and 12.5) returns an object of class <code>Class</code> (package <code>java.lang</code>)

	contains information about the object's type, such as its class name (returned by <code>Class</code> method <code>getName</code>).
<code>finalize</code>	This <code>protected</code> method is called by the garbage collector to perform termination housekeeping on an object just before the garbage collector reclaims the object's memory. Recall from Section 8.10 that it's unclear whether, or when, <code>finalize</code> will be called. For this reason, most programmers should avoid method <code>finalize</code> .
<code>clone</code>	This <code>protected</code> method, which takes no arguments and returns an <code>Object</code> reference, makes a copy of the object on which it's called. The default implementation performs a shallow copy—instance-variable values in one object are copied into another object of the same type. For reference types, only the references are copied. A typical overridden <code>clone</code> method's implementation would perform a deep copy that creates a new object for each reference-type instance variable. Implementing <code>clone</code> correctly is difficult. For this reason, its use is discouraged. Some industry experts suggest that object serialization be used instead. We discuss object serialization in Chapter 15 . Recall from Chapter 15 that arrays are objects. As a result, like all other objects, arrays inherit the members of <code>Object</code> . Every array has an overridden <code>clone</code> method that copies the array. However, because the array stores references to objects, the objects are not copied—a shallow copy is performed.
