

7.11 Multidimensional Arrays

Multidimensional arrays with two dimensions often represent *tables* of values with data arranged in *rows* and *columns*. To identify a particular table element, you specify *two* indices. *By convention*, the first identifies the element's row and the second its column. Arrays that require two indices to identify each element are called **two-dimensional arrays**. (Multidimensional arrays can have more than two dimensions.) Java does not support multidimensional arrays directly, but it allows you to specify one-dimensional arrays whose elements are also one-dimensional arrays, thus achieving the same effect. [Figure 7.16](#) illustrates a two-dimensional array named **a** with three rows and four columns (i.e., a three-by-four array). In general, an array with *m* rows and *n* columns is called an ***m*-by-*n* array**.

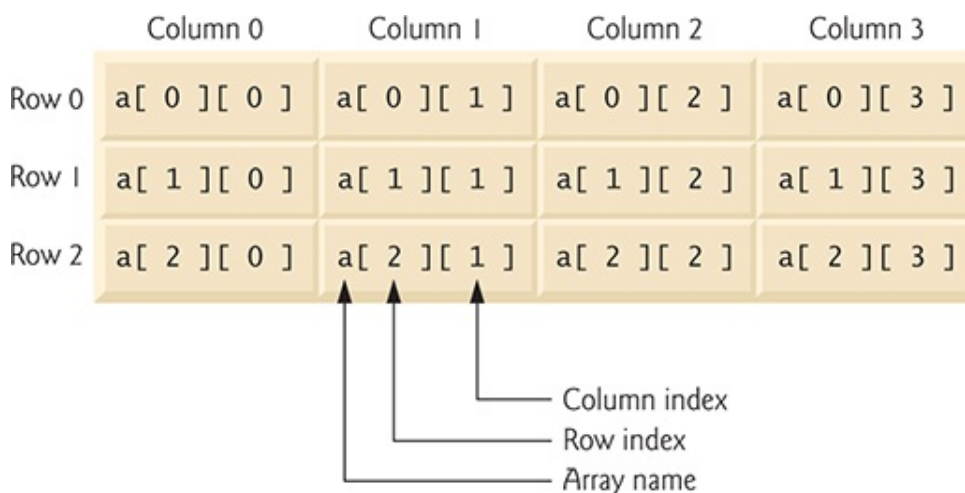

Fig. 7.16

Two-dimensional array with three rows and four columns.

Description

Every element in array **a** is identified in [Fig. 7.16](#) by an *array-access expression* of the form `a[row][column]`; **a** is the name of the array, and *row* and *column* are the indices that uniquely identify each element by row and column index. The element names in *row* 0 all have a *first* index of 0, and the element names in *column* 3 all have a *second* index of 3.

7.11.1 Arrays of One-Dimensional Arrays

Like one-dimensional arrays, multidimensional arrays can be initialized with array initializers in declarations. A two-dimensional array **b** with two rows and two columns could be declared and initialized with **nested array initializers** as follows:

```
int[][] b = {{1, 2}, {3, 4}};
```

The initial values are *grouped by row* in braces. So 1 and 2 initialize `b[0][0]` and `b[0][1]`, respectively, and 3 and 4 initialize `b[1][0]` and `b[1][1]`, respectively. The compiler counts the number of nested array initializers (represented by

sets of braces within the outer braces) to determine the number of *rows* in array **b**. The compiler counts the initializer values in the nested array initializer for a row to determine the number of *columns* in that row. As we'll see momentarily, this means that *rows can have different lengths*.

Multidimensional arrays are maintained as *arrays of one-dimensional arrays*. Therefore array **b** in the preceding declaration is actually composed of two separate one-dimensional arrays—one containing the values in the first nested initializer list `{1, 2}` and one containing the values in the second nested initializer list `{3, 4}`. Thus, array **b** itself is an array of two elements, each a one-dimensional array of `int` values.

7.11.2 Two-Dimensional Arrays with Rows of Different Lengths

The manner in which multidimensional arrays are represented makes them quite flexible. In fact, the lengths of the rows in array **b** are *not* required to be the same. For example,

```
int[][] b = {{1, 2}, {3, 4, 5}};
```

creates integer array **b** with two elements (determined by the number of nested array initializers) that represent the rows of

the two-dimensional array. Each element of `b` is a *reference* to a one-dimensional array of `int` variables. The `int` array for row `0` is a one-dimensional array with *two* elements (`1` and `2`), and the `int` array for row `1` is a one-dimensional array with *three* elements (`3`, `4` and `5`).

7.11.3 Creating Two-Dimensional Arrays with Array-Creation Expressions

A multidimensional array with the *same* number of columns in every row can be created with an array-creation expression. For example, the following line declares array `b` and assigns it a reference to a three-by-four array:

```
int[][] b = new int[3][4];
```

In this case, we use the literal values `3` and `4` to specify the number of rows and number of columns, respectively, but this is *not* required. Programs can also use variables to specify array dimensions, because `new` *creates arrays at execution time—not at compile time*. The elements of a multidimensional array are initialized when the array object is created.

A multidimensional array in which each row has a *different* number of columns can be created as follows:

```
int[][] b = new int[2][]; // create 2 rows
b[0] = new int[5]; // create 5 columns for row 0
b[1] = new int[3]; // create 3 columns for row 1
```

The preceding statements create a two-dimensional array with two rows. Row 0 has *five* columns, and row 1 has *three* columns.

7.11.4 Two-Dimensional Array Example: Displaying Element Values

Figure 7.17 demonstrates initializing two-dimensional arrays with array initializers and using nested **for** loops to **traverse** the arrays (i.e., manipulate *every* element of each array). Class `InitArray`'s `main` declares two arrays. The declaration of `array1` (line 7) uses nested array initializers of the *same* length to initialize the first row to the values 1, 2 and 3, and the second row to the values 4, 5 and 6. The declaration of `array2` (line 8) uses nested initializers of *different* lengths. In this case, the first row is initialized to two elements with the values 1 and 2, respectively. The second row is initialized to one element with the value 3. The third row is initialized to three elements with the values 4, 5 and 6, respectively.

```
1 // Fig. 7.17: InitArray.java
2 // Initializing two-dimensional arrays.
```

```

4    public class InitArray {
5        // create and output two-dimensional arrays
6        public static void main(String[] args) {
7            int[][] array1 = {{1, 2, 3}, {4, 5, 6}};
8            int[][] array2 = {{1, 2}, {3}, {4, 5, 6}};
9
10           System.out.println("Values in array1 by row
11           outputArray(array1); // displays array1 by
12
13           System.out.printf("%nValues in array2 by r
14           outputArray(array2); // displays array2 by
15           }
16
17           // output rows and columns of a two-dimension
18           public static void outputArray(int[][] array)
19               // loop through array's rows
20               for (int row = 0; row < array.length; row++)
21                   // loop through columns of current row
22                   for (int column = 0; column < array[row].length; column++)
23                       System.out.printf("%d ", array[row][column]);
24                   }
25
26           System.out.println();
27           }
28       }
29   }

```

Values in array1 by row are

```

1  2  3
4  5  6

```

Values in array2 by row are

```

1  2
3
4  5  6

```

Fig. 7.17

Initializing two-dimensional arrays.

Lines 11 and 14 call method `outputArray` (lines 18–28) to output the elements of `array1` and `array2`, respectively. Method `outputArray`'s parameter—`int[][] array`—indicates that the method receives a two-dimensional array. The nested `for` statement (lines 20–27) outputs the rows of a two-dimensional array. In the loop-continuation condition of the outer `for` statement, the expression `array.length` determines the number of rows in the array. In the inner `for` statement, the expression `array[row].length` determines the number of columns in the current row of the array. The inner `for` statement's condition enables the loop to determine the exact number of columns in each row. We demonstrate nested enhanced `for` statements in [Fig. 7.18](#).

7.11.5 Common Multidimensional-Array Manipulations Performed with `for` Statements

Many common array manipulations use `for` statements. As an example, the following `for` statement sets all the elements in row 2 of array `a` in [Fig. 7.16](#) to zero:

```
for (int column = 0; column < a[2].length; column++)  
    a[2][column] = 0;  
}
```

We specified row 2; therefore, we know that the *first* index is always 2 (0 is the first row, and 1 is the second row). This **for** loop varies only the *second* index (i.e., the column index). If row 2 of array **a** contains four elements, then the preceding **for** statement is equivalent to the assignment statements

```
a[2][0] = 0;  
a[2][1] = 0;  
a[2][2] = 0;  
a[2][3] = 0;
```

The following nested **for** statement totals the values of all the elements in array **a**:

```
int total = 0;  
for (int row = 0; row < a.length; row++) {  
    for (int column = 0; column < a[row].length; column++)  
        total += a[row][column];  
}
```

These nested **for** statements total the array elements *one row at a time*. The outer **for** statement begins by setting the **row** index to 0 so that the first row's elements can be totaled by the

inner `for` statement. The outer `for` then increments `row` to 1 so that the second row can be totaled. Then, the outer `for` increments `row` to 2 so that the third row can be totaled. The variable `total` can be displayed when the outer `for` statement terminates. In the next example, we show how to process a two-dimensional array in a similar manner using nested enhanced `for` statements.
