

7.12 Case Study: Class GradeBook Using a Two-Dimensional Array

In [Section 7.10](#), we presented class `GradeBook` ([Fig. 7.14](#)), which used a one-dimensional array to store student grades on a single exam. In most semesters, students take several exams. Professors are likely to want to analyze grades across the entire semester, both for a single student and for the class as a whole.

Storing Student Grades in a Two-Dimensional Array in Class `GradeBook`

[Figure 7.18](#) contains a `GradeBook` class that uses a two-dimensional array `grades` to store the grades of *several* students on *multiple* exams. Each *row* of the array represents a *single* student's grades for the entire course, and each *column* represents the grades of *all* the students who took a particular exam. Class `GradeBookTest` ([Fig. 7.19](#)) passes the array as an argument to the `GradeBook` constructor. In this example, we use a ten-by-three array for ten students' grades on three

exams. Five methods perform array manipulations to process the grades. Each method is similar to its counterpart in the earlier one-dimensional array version of `GradeBook` (Fig. 7.14). Method `getMinimum` (lines 39–55 of Fig. 7.18) determines the lowest grade of any student for the semester. Method `getMaximum` (lines 58–74) determines the highest grade of any student for the semester. Method `getAverage` (lines 77–87) determines a particular student’s semester average. Method `outputBarChart` (lines 90–121) outputs a grade bar chart for the entire semester’s student grades. Method `outputGrades` (lines 124–148) outputs the array in a tabular format, along with each student’s semester average.

145          double average = getAverage(grades[stu
146          System.out.printf("%9.2f%n", average);
              147      }
              148  }
              149  }
```

Fig. 7.18

GradeBook class using a two-dimensional array to store grades.

Methods `getMinimum` and `getMaximum`

Methods `getMinimum`, `getMaximum`, `outputBarChart` and `outputGrades` each loop through array `grades` by using nested `for` statements—for example, the nested enhanced `for` statement (lines 44–52) from the declaration of method `getMinimum`. The outer enhanced `for` statement iterates through the two-dimensional array `grades`, assigning successive rows to parameter `studentGrades` on successive iterations. The square brackets following the parameter name indicate that `studentGrades` refers to a one-dimensional `int` array—namely, a row in array `grades` containing one student's grades. To find the lowest overall

grade, the inner `for` statement compares the elements of the current one-dimensional array `studentGrades` to variable `lowGrade`. For example, on the first iteration of the outer `for`, row 0 of `grades` is assigned to parameter `studentGrades`. The inner enhanced `for` statement then loops through `studentGrades` and compares each `grade` value with `lowGrade`. If a grade is less than `lowGrade`, `lowGrade` is set to that grade. On the second iteration of the outer enhanced `for` statement, row 1 of `grades` is assigned to `studentGrades`, and the elements of this row are compared with variable `lowGrade`. This repeats until all rows of `grades` have been traversed. When execution of the nested statement is complete, `lowGrade` contains the lowest grade in the two-dimensional array. Method `getMaximum` works similarly to method `getMinimum`.

Method `outputBarChart`

Method `outputBarChart` in [Fig. 7.18](#) is nearly identical to the one in [Fig. 7.14](#). However, to output the overall grade distribution for a whole semester, the method here uses nested enhanced `for` statements (lines 97–101) to create the one-dimensional array `frequency` based on all the grades in the two-dimensional array. The rest of the code in each of the two `outputBarChart` methods that displays the chart is identical.

Method `outputGrades`

Method `outputGrades` (lines 124–148) uses nested `for` statements to output values of the array `grades` and each student's semester average. The output (Fig. 7.19) shows the result, which resembles the tabular format of a professor's physical grade book. Lines 129–131 of Fig. 7.18 print the column headings for each test. We use a counter-controlled `for` statement here so that we can identify each test with a number. Similarly, the `for` statement in lines 136–147 first outputs a row label using a counter variable to identify each student (line 137). Although array indices start at 0, lines 130 and 137 output `test + 1` and `student + 1`, respectively, to produce test and student numbers starting at 1 (see the output in Fig. 7.19). The inner `for` statement (lines 139–141 of Fig. 7.18) uses the outer `for` statement's counter variable `student` to loop through a specific row of array `grades` and output each student's test grade. An enhanced `for` statement can be nested in a counter-controlled `for` statement, and vice versa. Finally, line 145 obtains each student's semester average by passing the current row of `grades` (i.e., `grades[student]`) to method `getAverage`.

Method `getAverage`

Method `getAverage` (lines 77–87) takes one argument—a one-dimensional array of test results for a particular student. When line 145 calls `getAverage`, the argument is

`grades[student]`, which specifies that a particular row of the two-dimensional array `grades` should be passed to `getAverage`. For example, based on the array created in [Fig. 7.19](#), the argument `grades[1]` represents the three values (a one-dimensional array of grades) stored in row 1 of the two-dimensional array `grades`. Recall that a two-dimensional array is one whose elements are one-dimensional arrays. Method `getAverage` calculates the sum of the array elements, divides the total by the number of test results and returns the floating-point result as a `double` value (line 86 of [Fig. 7.18](#)).

Class GradeBookTest That Demonstrates Class GradeBook

[Figure 7.19](#) creates an object of class `GradeBook` using the two-dimensional array of `ints` named `gradesArray` (declared and initialized in lines 8–17). Lines 19–20 pass a course name and `gradesArray` to the `GradeBook` constructor. Lines 21–22 display a welcome message containing the course name, then line 23 invokes `myGradeBook`'s `processGrades` method to display a report summarizing the students' grades for the semester.

```

22           myGradeBook.getCourseName());
23       myGradeBook.processGrades();
24       }
25   }

```

Welcome to the grade book for
CS101 Introduction to Java Programming

The grades are:

	Test 1	Test 2	Test 3	Average
Student 1	87	96	70	84.33
Student 2	68	87	90	81.67
Student 3	94	100	90	94.67
Student 4	100	81	82	87.67

Student 5	83	65	85	77.67
Student 6	78	87	65	76.67
Student 7	85	75	83	81.00
Student 8	91	94	100	95.00
Student 9	76	72	84	77.33
Student 10	87	93	73	84.33

```

Lowest grade in the grade book is 65
Highest grade in the grade book is 100

```

```

Overall grade distribution:

```

```

    00-09:
    10-19:
    20-29:
    30-39:
    40-49:
    50-59:
    60-69: ***
    70-79: *
    80-89: *
    90-99: *
    100: ***

```

Fig. 7.19

GradeBookTest creates GradeBook object using a two-dimensional array of grades, then invokes method processGrades to analyze them.
