

7.6 Case Study: Card Shuffling and Dealing Simulation

The examples in the chapter thus far have used arrays containing elements of primitive types. Recall from [Section 7.2](#) that the elements of an array can be either primitive types or reference types. This section uses random-number generation and an array of reference-type elements, namely objects representing playing cards, to develop a class that simulates card shuffling and dealing. This class can then be used to implement applications that play specific card games. The exercises at the end of the chapter use the classes developed here to build a simple poker application.

We first develop class `Card` ([Fig. 7.9](#)), which represents a playing card that has a face (e.g., "Ace", "Deuce", "Three", ..., "Jack", "Queen", "King") and a suit (e.g., "Hearts", "Diamonds", "Clubs", "Spades"). Next, we develop the `DeckOfCards` class ([Fig. 7.10](#)), which creates a deck of 52 playing cards in which each element is a `Card` object. We then build a test application ([Fig. 7.11](#)) that demonstrates class `DeckOfCards`'s card shuffling and dealing capabilities.

Class Card

Class Card (Fig. 7.9) contains two `String` instance variables—`face` and `suit`—that are used to store references to the face name and suit name for a specific Card. The constructor for the class (lines 9–12) receives two `Strings` that it uses to initialize `face` and `suit`. Method `toString` (lines 15–17) creates a `String` consisting of the `face` of the card, the `String` "of" and the `suit` of the card.¹ Card's `toString` method can be invoked *explicitly* to obtain a string representation of a Card object (e.g., "Ace of Spades"). The `toString` method of an object is called *implicitly* when the object is used where a `String` is expected (e.g., when `printf` outputs the object as a `String` using the `%s` format specifier or when the object is concatenated to a `String` using the `+` operator). For this behavior to occur, `toString` must be declared with the header shown in Fig. 7.9.

¹. You'll learn in Chapter 9 that when we provide a custom `toString` method for a class, we are actually "overriding" a version of that method supplied by class `Object` from which all Java classes "inherit." As of Chapter 9, every method we explicitly override will be preceded by the "annotation" `@Override`, which prevents a common programming error.

```
1 // Fig. 7.9: Card.java
2 // Card class represents a playing card.
3
4 public class Card {
5     private final String face; // face of card (""
6     private final String suit; // suit of card (""
7
8     // two-argument constructor initializes card'
9     public Card(String cardFace, String cardSuit)
```

```
10         this.face = cardFace; // initialize face o
11         this.suit = cardSuit; // initialize suit o
12     }
13
14     // return String representation of Card
15     public String toString() {
16         return face + " of " + suit;
17     }
18 }
```

Fig. 7.9

Card class represents a playing card.

Class DeckOfCards

Class **DeckOfCards** ([Fig. 7.10](#)) creates and manages an array of **Card** references. The named constant **NUMBER_OF_CARDS** (line 8) specifies the number of **Cards** in a deck (52). Line 10 declares and initializes an instance variable named **deck** that refers to a new array of **Cards** that has **NUMBER_OF_CARDS** (52) elements—the **deck** array’s elements are **null** by default. Recall from [Chapter 3](#) that **null** represents a “reference to nothing,” so no **Card** objects exist yet. An array of a *reference* type is declared like any other array. Class **DeckOfCards** also declares **int** instance variable **currentCard** (line 11), representing the sequence number (0–51) of the next **Card** to be dealt from the **deck**.

array.

```
1 // Fig. 7.10: DeckOfCards.java
2 // DeckOfCards class represents a deck of playing cards
3 import java.security.SecureRandom;
4
5 public class DeckOfCards {
6     // random number generator
7     private static final SecureRandom randomNumbers =
8     private static final int NUMBER_OF_CARDS = 52
9
10    private Card[] deck = new Card[NUMBER_OF_CARDS];
11    private int currentCard = 0; // index of next card
12
13    // constructor fills deck of Cards
14    public DeckOfCards() {
15        String[] faces = {"Ace", "Deuce", "Three",
16                          "Seven", "Eight", "Nine", "Ten", "Jack"};
17        String[] suits = {"Hearts", "Diamonds", "Clubs", "Spades"};
18
19        // populate deck with Card objects
20        for (int count = 0; count < deck.length; count++) {
21            deck[count] =
22                new Card(faces[count % 13], suits[(count / 13) % 4]);
23        }
24    }
25
26    // shuffle deck of Cards with one-pass algorithm
27    public void shuffle() {
28        // next call to method dealCard should start at index 0
29        currentCard = 0;
30
31        // for each Card, pick another random Card
32        for (int first = 0; first < deck.length; first++) {
33            // select a random number between 0 and NUMBER_OF_CARDS - 1
34            int second = randomNumbers.nextInt(NUMBER_OF_CARDS);
35
36            // swap current Card with randomly selected Card
37            Card temp = deck[first];
38            deck[first] = deck[second];
39            deck[second] = temp;
40        }
41    }
42
43    // return current Card
44    public Card dealCard() {
45        if (currentCard == NUMBER_OF_CARDS)
46            return null;
47        else
48            return deck[currentCard++];
49    }
50
51    // print deck of Cards
52    public void printDeck() {
53        for (int i = 0; i < deck.length; i++)
54            System.out.println(deck[i]);
55    }
56}
```

```
38         deck[first] = deck[second];
39         deck[second] = temp;
40         }
41     }
42
43     // deal one Card
44     public Card dealCard() {
45         // determine whether Cards remain to be de
46         if (currentCard < deck.length) {
47             return deck[currentCard++]; // return c
48         }
49         else {
50             return null; // return null to indicate
51         }
52     }
53 }
```

Fig. 7.10

DeckOfCards class represents a deck of playing cards.

DeckOfCards Constructor

The class's constructor uses a **for** statement (lines 20–23) to fill the **deck** instance variable with **Card** objects. The loop initializes control variable **count** to 0 and loops while **count** is less than **deck.length**, causing **count** to take on each integer value from 0 through 51 (the **deck** array's indices). Each **Card** is instantiated and initialized with two **Strings**—one from the **faces** array (which contains the

Strings "Ace" through "King") and one from the `suits` array (which contains the Strings "Hearts", "Diamonds", "Clubs" and "Spades"). The calculation `count % 13` always results in a value from 0 to 12 (the 13 indices of the `faces` array in lines 15–16), and the calculation `count / 13` always results in a value from 0 to 3 (the four indices of the `suits` array in line 17). When the loop completes, `deck` contains the `Cards` with faces "Ace" through "King" in order for each suit (13 "Hearts", then 13 "Diamonds", then 13 "Clubs", then 13 "Spades"). We use arrays of `Strings` to represent the faces and suits in this example. In [Exercise 7.34](#), we ask you to modify this example to use arrays of `enum` constants to represent the faces and suits.

DeckOfCards Method shuffle

Method `shuffle` (lines 27–41) shuffles the `Cards` in the deck. The method loops through all 52 `Cards` (array indices 0 to 51). For each `Card`, line 34 selects a random index between 0 and 51 to select another `Card`. Next, lines 37–39 swap the current `Card` and the randomly selected `Card` in the array. The extra variable `temp` (line 37) temporarily stores one of the two `Card` objects being swapped. After the `for` loop terminates, the `Card` objects are randomly ordered. A total of only 52 swaps are made in a single pass of the entire array, and the array of `Card` objects is shuffled!

The swap in lines 37–39 cannot be performed with only the two statements

```
deck[first] = deck[second];
deck[second] = deck[first];
```

If `deck[first]` is the "Ace" of "Spades" and `deck[second]` is the "Queen" of "Hearts", after the first assignment, both array elements contain the "Queen" of "Hearts" and the "Ace" of "Spades" is lost—so, the extra variable `temp` is needed.

[*Note:* It's recommended that you use a so-called *unbiased* shuffling algorithm for real card games. Such an algorithm ensures that all possible shuffled card sequences are equally likely to occur. [Exercise 7.35](#) asks you to research the popular unbiased Fisher-Yates shuffling algorithm and use it to reimplement the `DeckOfCards` method `shuffle`.]

DeckOfCards Method dealCard

Method `dealCard` (lines 44–52) deals one `Card` in the array. Recall that `currentCard` indicates the index of the next `Card` to be dealt (i.e., the `Card` at the *top* of the deck). Thus, line 46 compares `currentCard` to the length of the `deck` array. If the `deck` is not empty (i.e., `currentCard` is

less than 52), line 47 returns the “top” Card and postincrements currentCard to prepare for the next call to dealCard—otherwise, line 50 returns null.

Shuffling and Dealing Cards

Figure 7.11 demonstrates class DeckOfCards. Line 7 creates a DeckOfCards object named myDeckOfCards. The DeckOfCards constructor creates the deck with the 52 Card objects in order by suit and face. Line 8 invokes myDeckOfCards’s shuffle method to rearrange the Card objects. Lines 11–18 deal all 52 Cards and print them in four columns of 13 Cards each. Line 13 deals one Card object by invoking myDeckOfCards’s dealCard method, then displays the Card left justified in a field of 19 characters. When a Card is output as a String, the Card’s toString method (Fig. 7.9) is implicitly invoked. Lines 15–17 in Fig. 7.11 start a new line after every four Cards.

```
1 // Fig. 7.11: DeckOfCardsTest.java
2 // Card shuffling and dealing.
3
4 public class DeckOfCardsTest {
5     // execute application
6     public static void main(String[] args) {
7         DeckOfCards myDeckOfCards = new DeckOfCard
8         myDeckOfCards.shuffle(); // place Cards in
9
10        // print all 52 Cards in the order in whic
11        for (int i = 1; i <= 52; i++) {
12            // deal and display a Card
```

```

13         System.out.printf("%-19s", myDeckOfCard
14
15         if (i % 4 == 0) { // output a newline a
16             System.out.println();
17         }
18     }
19 }
20 }
```

Six of Spades	Eight of Spades	Six of Clubs	Nine of Hearts
Queen of Hearts	Seven of Clubs	Nine of Spades	King of Hearts
Three of Diamonds	Deuce of Clubs	Ace of Hearts	Ten of Spades
Four of Spades	Ace of Clubs	Seven of Diamonds	Four of Hearts

Card shuffling and dealing.

Preventing NullPointerExceptions

In Fig. 7.10, we created a `deck` array of 52 `Card` references —by default, each element of a reference-type array created with `new` is initialized to `null`. Similarly, reference-type fields of a class are also initialized to `null` by default. A `NullPointerException` occurs when you try to call a method on a `null` reference. In industrial-strength code, ensuring that references are not `null` before you use them to call methods prevents `NullPointerExceptions`.
